**Abstract**

A finite sequence \( \vec{a} = \langle a_i \rangle_{i=1}^m \) in \( \mathbb{Z} \setminus \{0\} \) is *compressed* provided \( a_i \neq a_{i+1} \) for \( i < m \). It is known that if \( \vec{a} = \langle a_i \rangle_{i=1}^m \) and \( \vec{b} = \langle b_i \rangle_{i=1}^k \) are compressed sequences in \( \mathbb{Z} \setminus \{0\} \), then there exist idempotents \( p \) and \( q \) in \( \beta \mathbb{Q}_d \setminus \{0\} \) such that \( a_1p + a_2p + \ldots + a_mp = b_1q + b_2q + \ldots + b_kq \) if and only if \( \vec{b} \) is a rational multiple of \( \vec{a} \). In fact, if \( \vec{b} \) is not a rational multiple of \( \vec{a} \), then there is a partition of \( \mathbb{Q} \setminus \{0\} \) into two cells, neither of which is a member of \( \vec{b} \) for any idempotents \( p \) and \( q \) in \( \beta \mathbb{Q}_d \setminus \{0\} \).

(Here \( \beta \mathbb{Q}_d \) is the Stone-Čech compactification of the set of rational numbers with the discrete topology.)

In this paper we extend these results to direct sums of \( \mathbb{Q} \). As a corollary, we show that if \( \vec{b} \) is not a rational multiple of \( \vec{a} \) and \( G \) is any torsion free commutative group, then there do not exist idempotents \( p \) and \( q \) in \( \beta G_d \setminus \{0\} \) such that \( a_1p + a_2p + \ldots + a_mp = b_1q + b_2q + \ldots + b_kq \). We also show that for direct sums of finitely many copies of \( \mathbb{Q} \) we can separate the corresponding...
Milliken-Taylor systems, with a similar but weaker result for the direct sum of countably many copies of \( \mathbb{Q} \).

**Key words:** Stone-Čech Compactification, linear expressions, Milliken-Taylor systems

1. Introduction

We are investigating the following two questions in this paper. (We will describe the operation on \( \beta G_d \) and the action of \( \mathbb{Z} \) on \( \beta G_d \) later in this introduction.)

**Question 1.1.** Which commutative groups \( (G,+) \) have the property that whenever \( \vec{a} = \langle a_1, a_2, \ldots, a_m \rangle \) and \( \vec{b} = \langle b_1, b_2, \ldots, b_k \rangle \) are compressed sequences in \( \mathbb{Z} \setminus \{0\} \) which are not rational multiples of each other, there do not exist idempotents \( p \) and \( q \) in \( \beta G_d \setminus \{0\} \) such that \( a_1p + a_2p + \ldots + a_mp = b_1q + b_2q + \ldots + b_kq \)?

**Question 1.2.** Which commutative groups \( (G,+) \) have the property that whenever \( \vec{a} = \langle a_1, a_2, \ldots, a_m \rangle \) and \( \vec{b} = \langle b_1, b_2, \ldots, b_k \rangle \) are compressed sequences in \( \mathbb{Z} \setminus \{0\} \) which are not rational multiples of each other, there is a partition of \( G \setminus \{0\} \) into finitely many cells such that there do not exist idempotents \( p \) and \( q \) in \( \beta G_d \setminus \{0\} \) and one cell of the partition which is a member of both \( a_1p + a_2p + \ldots + a_mp \) and \( b_1q + b_2q + \ldots + b_kq \)?

The motivation for these questions comes from the ability to separate Milliken-Taylor systems. Given a set \( X \), we write \( P_f(X) \) for the set of finite nonempty subsets of \( X \).

**Definition 1.3.** Let \( \vec{a} = \langle a_1, a_2, \ldots, a_m \rangle \) be a compressed sequence in \( \mathbb{Z} \setminus \{0\} \) and let \( \langle x_n \rangle_{n=1}^{\infty} \) be a sequence in a commutative group \( (G,+) \). The Milliken-Taylor system generated by \( \vec{a} \) and \( \langle x_n \rangle_{n=1}^{\infty} \) is

\[
MT(\vec{a}, \langle x_n \rangle_{n=1}^{\infty}) = \{ \sum_{i=1}^{m} a_i \cdot \sum_{n \in F_i} x_n : F_1, F_2, \ldots, F_m \in P_f(\mathbb{N}) \text{ with } \max F_i < \min F_{i+1} \text{ for } i < m \}.
\]

Milliken-Taylor systems are partition regular. That is, given \( \vec{a} \), if a commutative group \( G \) is partitioned into finitely many cells, then there is one cell which contains \( MT(\vec{a}, \langle x_n \rangle_{n=1}^{\infty}) \) for some sequence \( \vec{x} \). (In the alternative coloring terminology common in Ramsey Theory, if \( G \) is finitely colored there is a sequence \( \langle x_n \rangle_{n=1}^{\infty} \) such that \( MT(\vec{a}, \langle x_n \rangle_{n=1}^{\infty}) \) is monochromatic.) The Milliken-Taylor systems are so named because the fact that they are partition regular is an immediate consequence of the Milliken-Taylor Theorem ([4, Theorem 2.2] and [5, Lemma 2.2]).

The relationship between Milliken-Taylor systems and linear expressions in \( \beta G_d \) is given by the following theorem.
Theorem 1.4. Let $G$ be a commutative group, let $\vec{a} = \langle a_1, a_2, \ldots, a_m \rangle$ be a compressed sequence in $\mathbb{Z} \setminus \{0\}$, and let $A \subseteq G$. There is a sequence $\langle x_n \rangle_{n=1}^{\infty}$ in $G$ such that $MT(\vec{a}, \langle x_n \rangle_{n=1}^{\infty}) \subseteq A$ if and only if there is an idempotent $p \in \beta G_d$ such that $A \in a_1p + a_2p + \ldots + a_mp$.

Proof. [3, Theorem 1.5].

Given a compressed sequence $\vec{a}$ in $\mathbb{Z} \setminus \{0\}$, there is a matrix $M$ such that $MT(\vec{a}, \langle x_n \rangle_{n=1}^{\infty})$ is the set of entries of $M\vec{x}$, where $\vec{x} = \begin{pmatrix} x_1 \\ x_2 \\ \vdots \end{pmatrix}$. These matrices are examples of image partition regular matrices and were some of the first known examples of infinite image partition regular matrices. Finite image partition regular matrices with rational entries have the property that given any finite partition of $\mathbb{N}$, there is one cell which contains an image of all of these matrices. (See [2, Theorem 15.24].) By way of contrast, there is the following theorem.

Theorem 1.5. Let $\vec{a} = \langle a_1, a_2, \ldots, a_m \rangle$ and $\vec{b} = \langle b_1, b_2, \ldots, b_k \rangle$ be compressed sequences in $\mathbb{Z} \setminus \{0\}$. The following statements are equivalent.

(a) Whenever $\mathbb{Z} \setminus \{0\}$ is finitely colored, there exist sequences $\langle x_n \rangle_{n=1}^{\infty}$ and $\langle y_n \rangle_{n=1}^{\infty}$ in $\mathbb{Z} \setminus \{0\}$ such that $MT(\vec{a}, \langle x_n \rangle_{n=1}^{\infty}) \cup MT(\vec{b}, \langle y_n \rangle_{n=1}^{\infty})$ is monochromatic.

(b) Whenever $\mathbb{Q} \setminus \{0\}$ is finitely colored, there exist sequences $\langle x_n \rangle_{n=1}^{\infty}$ and $\langle y_n \rangle_{n=1}^{\infty}$ in $\mathbb{Q} \setminus \{0\}$ such that $MT(\vec{a}, \langle x_n \rangle_{n=1}^{\infty}) \cup MT(\vec{b}, \langle y_n \rangle_{n=1}^{\infty})$ is monochromatic.

(c) There exist idempotents $p$ and $q$ in $\beta \mathbb{Z} \setminus \{0\}$ such that $a_1p + a_2p + \ldots + a_mp = b_1q + b_2q + \ldots + b_kq$.

(d) There exist idempotents $p$ and $q$ in $\beta \mathbb{Q_d} \setminus \{0\}$ such that $a_1p + a_2p + \ldots + a_mp = b_1q + b_2q + \ldots + b_kq$.

(e) Whenever $\mathbb{Z} \setminus \{0\}$ is finitely colored, there exist idempotents $p$ and $q$ in $\beta \mathbb{Z} \setminus \{0\}$ and a color class which is a member of both $a_1p + a_2p + \ldots + a_mp$ and $b_1q + b_2q + \ldots + b_kq$.

(f) Whenever $\mathbb{Q} \setminus \{0\}$ is finitely colored, there exist idempotents $p$ and $q$ in $\beta \mathbb{Q_d} \setminus \{0\}$ and a color class which is a member of both $a_1p + a_2p + \ldots + a_mp$ and $b_1q + b_2q + \ldots + b_kq$.

(g) The sequence $\vec{b}$ is a rational multiple of $\vec{a}$.

Proof. The equivalence of (a) with (c) and the equivalence of (b) with (f) follow from Theorem 1.4. It is trivial that (c) implies (e) and that (d) implies (f). The fact that (g) implies both (c) and (d) follows from the fact that if $p$ is an idempotent in $\beta \mathbb{Z}$ and $\alpha \in \mathbb{Q} \setminus \{0\}$, then $\alpha p$ is also an idempotent in $\beta \mathbb{Z}$. (For
the details of this argument see [2, Lemma 15.23.2].) Finally, the fact that \((a)\) implies \((g)\) follows from [1, Theorem 3.1] and the fact that \((b)\) implies \((g)\) is [3, Theorem 4.3].

We utilize the algebraic structure of \(\beta G_d\), the Stone-Čech compactification of \(G_d\), where \((G, +)\) is a commutative group and the subscript indicates that we are giving \(G\) the discrete topology. We take the points of \(\beta G_d\) to be the ultrafilters on \(G\), with the points of \(G\) being identified with the principal ultrafilters. Given \(A \subseteq G\), \(\mathcal{A} = \{p \in \beta G_d : A \in p\}\). The operation \(+\) on \(G\) extends to an operation on \(\beta G_d\), also denoted by \(+\), so that \((\beta G_d, +)\) is a right topological semigroup (meaning that for each \(p \in \beta G_d\), the function \(\rho_p : \beta G_d \to \beta G_d\) is continuous, where \(\rho_p(q) = q + p\)) with \(G\) contained in its topological center (meaning that for each \(x \in G\), the function \(\lambda_x : \beta G_d \to \beta G_d\) is continuous, where \(\lambda_x(q) = x + q\)). Given \(p\) and \(q\) in \(\beta G_d\) and \(A \subseteq G\), \(A \in p + q\) if and only if \(\{x \in S : -x + A \in q\}\) \(\in p\). We let \(G^* = \beta G_d \setminus G\). Then \(G^*\) is a compact subsemigroup – in fact a two sided ideal – of \(\beta G_d\). As does any compact right topological semigroup, \(G^*\) has idempotents. See [2, Part I] for an elementary introduction to the algebraic structure of \(\beta G_d\).

The reader should be cautioned that, even though we denote the operation on \(\beta G_d\) by \(+\), the operation is not commutative. In fact, by [2, Theorem 6.54], the center of \((\beta G_d, +)\) is \(G\).

Given \(a \in \mathbb{Z} \setminus \{0\}\) and \(x \in G\), we let \(ax\) have its usual meaning – that is the sum of \(x\) with itself \(a\) times if \(a > 0\) and the inverse of \((-a)x\) if \(a < 0\). If \(a \in \mathbb{Z} \setminus \{0\}\) and \(p \in G^*\), we define \(ap = \tilde{l}_a(p)\) where \(l_a : G \to G\) is defined as \(l_a(x) = ax\) and \(\tilde{l}_a : \beta G_d \to \beta G_d\) is its continuous extension. Thus, for example, if \(p \in G^*\), then \(2p\) does not mean \(p + p\). (In \(\beta \mathbb{Z}\), by [2, Theorem 13.18], there is no \(p \in \mathbb{Z}^*\) such that \(2p = p + p\).) For each \(A \subseteq S\) and each \(a \in \mathbb{Z} \setminus \{0\}\), \(A \in ap\) if and only if \(a^{-1}A \in p\), where \(a^{-1}A = \{x \in G : ax \in A\}\).

In Section 2 we prove that if \(\kappa\) is any cardinal greater than 0, and \(T = \bigoplus_{\sigma \leq \kappa} \mathbb{Q}\), then we can separate linear expressions of the form \(a_1p + a_2p + \ldots + a_mp\) and \(b_1q + b_2q + \ldots + b_kq\) whenever \(\tilde{b}\) is not a rational multiple of \(\tilde{a}\) and \(p\) and \(q\) are idempotents living at infinity. And we derive some consequences of this fact, including the fact mentioned in the abstract that for any torsion free commutative group \(G\), there do not exist idempotents \(p\) and \(q\) in \(\beta G_d \setminus \{0\}\) with \(a_1p + a_2p + \ldots + a_mp = b_1q + b_2q + \ldots + b_kq\). The results of Section 2 show that we can separate Milliken-Taylor systems generated by strongly increasing sequences, that is sequences with the maximum of support of each term less than the minimum of support of the succeeding term.

In Section 3 we derive some results involving separating Milliken-Taylor systems. If \(\kappa\) is finite, these are the strongest possible. If \(\kappa = \omega\), we show that one can prevent three Milliken-Taylor systems from ending up in the same cell of a partition of \(T\).
2. Separating linear expressions in $\beta T$

We shall use coloring terminology in this section. A finite coloring of a set $X$ is a function with finite range whose domain is $X$. If $\psi$ is a finite coloring of $X$, then $D$ is a color class of $\psi$ if and only if there is some $i$ in the range of $\psi$ such that $D = \psi^{-1}\{i\}$.

The following easy lemma is presumably well known.

**Lemma 2.1.** Let $F$ be a finite subset of $\mathbb{Q} \setminus \{0\}$. There is a finite coloring $\psi$ of $\mathbb{Q} \setminus \{0\}$ such that, if $x, y \in \mathbb{Q} \setminus \{0\}$, $a, b \in F$, $\psi(x) = \psi(y)$, and $a \neq b$, then $\psi(ax) = \psi(ay)$, but $\psi(ax) \neq \psi(by)$.

**Proof.** Let $H = \{|a| : a \in F\}$. We first note that it suffices to get a finite coloring $\mu$ of $\mathbb{Q}^+ = \{x \in \mathbb{Q} : x > 0\}$ such that if $x, y \in \mathbb{Q}^+$, $a, b \in H$, $\mu(x) = \mu(y)$, and $a \neq b$, then $\mu(ax) = \mu(bx)$ but $\mu(ax) \neq \mu(by)$. For then one can define a coloring $\psi$ of $\mathbb{Q} \setminus \{0\}$ so that for $x, y \in \mathbb{Q} \setminus \{0\}$, $\psi(x) = \psi(y)$ if and only if either (1) $x > 0$, $y > 0$, and $\mu(x) = \mu(y)$ or (2) $x < 0$, $y < 0$, and $\mu(x) = \mu(y)$.

Let $P$ be the set of primes that occur in the prime factorization of any member of $H$ and let $k$ be the largest integer such that there is some $p \in P$ such that $p^k$ or $p^{-k}$ occurs in the prime factorization of some member of $H$. Define a finite coloring $\mu$ of $\mathbb{Q}^+$ so that for $x, y \in \mathbb{Q}^+$, $\mu(x) = \mu(y)$ if and only if for all $p \in P$, if $p^r$ and $p^k$ are the powers of $p$ in the prime factorizations of $x$ and $y$ respectively, then $r \equiv l \pmod{2k + 1}$.

**Definition 2.2.** Let $\kappa > 0$ be an ordinal and let $T = \bigoplus_{\sigma < \kappa} \mathbb{Q}$. For $x \in T$, $\text{supp}(x) = \{\sigma < \kappa : x_\sigma \neq 0\}$. For $x \in T \setminus \{0\}$, $\delta(x) = \text{min} \ \text{supp}(x)$ and $\delta(x) = \text{max} \ \text{supp}(x)$. For $x, y \in T \setminus \{0\}$, we write $x \ll y$ if and only if $\delta(x) < \delta(y)$. An idempotent $r \in \beta T_\kappa$ is strongly increasing if $r$ has a member $R \subseteq T \setminus \{0\}$ with the property that, for every $x \in R$, $\{y \in R : x \ll y\} \in r$. A sequence $\langle x_n \rangle_{n=1}^\infty$ in $T \setminus \{0\}$ is strongly increasing if and only if for each $n \in \mathbb{N}$, $x_n \ll x_{n+1}$.

We shall assume throughout that $T$ has the discrete topology. (So we will write $\beta T$ rather than $\beta T_\kappa$.) We will use the fact from [2, Lemma 5.11] that if $\langle x_n \rangle_{n=1}^\infty$ is any sequence in $T$, there is an idempotent in $\bigcap_{l=1}^\infty \text{FS}(\langle x_n \rangle_{n=1}^\infty)$, where $\text{FS}(\langle x_n \rangle_{n=1}^\infty) = \{x \in T : x \in P_{T_\kappa}(\{l, l+1, l+2, \ldots\})\}$. Note that, if $\langle x_n \rangle_{n=1}^\infty$ is strongly increasing, every idempotent in $\bigcap_{l=1}^\infty \text{FS}(\langle x_n \rangle_{n=1}^\infty)$ is strongly increasing. (If $p \in \bigcap_{l=1}^\infty \text{FS}(\langle x_n \rangle_{n=1}^\infty)$, then $\text{FS}(\langle x_n \rangle_{n=1}^\infty)$ is as required for the definition of strongly increasing idempotent.)

If $p$ is an idempotent in $\beta T$ and $P \in p$, we put $P^* = \{x \in P : x + p \in P\}$. Then $P^* \in p$ and by [2, Lemma 4.14], for any $x \in P^*$, $-x + P^* \in p$.

The rest of this section is devoted to the proof of the following theorem and some of its consequences. That proof uses a modification of the gap counting technique used in [1]. The proof of Theorem 2.3 will include the statement and proof of four lemmas.

**Theorem 2.3.** Let $k, m \in \mathbb{N}$ and let $\kappa$ be an infinite cardinal. Let $\bar{a} = \langle a_1, a_2, \ldots, a_m \rangle$ and $\bar{b} = \langle b_1, b_2, \ldots, b_k \rangle$ be compressed sequences in $\mathbb{Z} \setminus \{0\}$ such...
Lemma 2.7. Let \( r \) be a strongly increasing idempotent in \( \beta T \), let \( u, v \in K \), and let \( c \in A \cup B \). If \( u = \tilde{\theta}_1(cr) \) and \( v = \tilde{\theta}_2(cr) \), then \( \tilde{\varphi}_{u,v}(cr) = -1 \). Otherwise \( \tilde{\varphi}_{u,v}(cr) = 0 \).
Definition 2.9. mod 2 following definition, as well as in the proof of Lemma 2.10, all congruences are
Proof. Let \( E \) be a member of \( r \) on which the functions \( x \mapsto \theta_1(cx), x \mapsto \theta_2(cx) \) and \( x \mapsto \varphi_{u,v}(cx) \) are constant. Recall that \( E^* = \{ z \in E : -z + E \in r \} \in r \). Choose \( x,y \in E^* \) such that \( x + y \in E^* \) and \( x \ll y \). Then by Lemma 2.6, 
\[ \varphi_{u,v}(cx + cy) \equiv \varphi_{u,v}(cx) + \varphi_{u,v}(cy) + h \pmod{2k+1} \]
where
\[ h = \begin{cases} 
1 & \text{if } u = \theta_1(cx) \text{ and } v = \theta_2(cy); \\
0 & \text{otherwise}. 
\end{cases} \]

So our claim follows from the fact that \( \tilde{\varphi}_{u,v}(cx) = \varphi_{u,v}(cx) = \varphi_{u,v}(cy) = \varphi_{u,v}(cx + cy) \). \( \square \)

Lemma 2.8. Let \( r \) be a strongly increasing idempotent in \( \beta T \). Let \( s \in \{2, 3, \ldots, k\} \), and let \( \tilde{c} = \langle c_1, c_2, \ldots, c_s \rangle \) be a compressed sequence in \( A \cup B \). Let \( R \) denote a member of \( r \) on which the functions \( \theta_1 \) and \( \theta_2 \) are constant, as well as all the functions of the form \( x \mapsto \varphi_{u,v}(c_j x) \), where \( u,v \in K \) and \( i \in \{1, 2, \ldots, s\} \). Also, let \( R \) have the property that, for each \( y \in R \), \( \{ z \in R : y \ll z \} \in r \).

Proof. Let \( (u,v) \in K^2 \) be given. By Lemma 2.6, 
\[ \varphi_{u,v}(x) = \sum_{i=1}^{s} \varphi_{u,v}(c_i w_i) + h \pmod{2k+1}, \]
where \( h = \left| \{ i \in \{1, 2, \ldots, s-1 \} : u = \theta_1(c_i w_i) \text{ and } v = \theta_2(c_{i+1} w_{i+1}) \} \right| \).
If there is no \( i \in \{1, 2, \ldots, s-1\} \) such that \( u = \theta_1(c_i w_i) \) and \( v = \theta_2(c_{i+1} w_{i+1}) \), then \( h = 0 \) and by Lemma 2.7, \( \varphi_{u,v}(c_j w_i) \in \{-1,0,1\} \) for each \( i \in \{1, 2, \ldots, s\} \).

So assume we have some \( i \in \{1, 2, \ldots, s-1\} \) such that \( u = \theta_1(c_i w_i) \) and \( v = \theta_2(c_{i+1} w_{i+1}) \). We claim that for each \( j \in \{1, 2, \ldots, s\} \), \( \varphi_{u,v}(c_j w_j) = 0 \). So suppose instead that we have some \( j \in \{1, 2, \ldots, t\} \) such that \( \varphi_{u,v}(c_j w_j) \neq 0 \). Then by Lemma 2.7, \( u = \theta_1(c_j w_j) \) and \( v = \theta_2(c_j w_j) \). Now \( c_i \neq c_{i+1} \) so either \( c_i \neq c_j \) or \( c_{i+1} \neq c_j \). In the first case, \( \theta_1(w_i) = \theta_1(w_j) \) so \( u = \theta_1(c_i w_i) \neq \theta_1(c_j w_j) = u \), a contradiction. In the second case, \( \theta_2(w_{i+1}) = \theta_2(w_j) \) so \( v = \theta_2(c_{i+1} w_{i+1}) \neq \theta_2(c_j w_j) = v \), a contradiction. \( \square \)

We now introduce some notation to assist us in our counting of gaps. In the following definition, as well as in the proof of Lemma 2.10, all congruences are \( \pmod{2k+1} \). So when we write \( |X| \equiv |Y| \) we mean \( |X| \equiv |Y| \pmod{2k+1} \).

Definition 2.9. Let \( x \in T \setminus \{0\} \).

(a) \( P(x) = \{(u,v) \in K^2 : \varphi_{u,v}(x) \in \{1, 2, \ldots, k\}\} \).

(b) \( G_P(x) = \{(t,u,v) \in G(x) : (u,v) \in P(x)\} \).

(c) For \( t \in \text{supp}(x) \), \( L_t(x) = \{(t',u',v') \in G_P(x) : t' < t\} \).

(d) For \( l \in \{0, 1, \ldots, k-1\} \), 
\[ S_l(x) = \{(t,u,v) \in G_P(x) : |L_t(x)| \equiv l \}. \]
(e) For \( l \in \{0, 1, \ldots, k - 1\} \), \( T_l(x) = \{(u, v) \in K^2 : \{t \in \kappa : (t, u, v) \in S_l(x)\} = 1\} \).

(f) For \( F \subseteq K^2 \), \( d \in \{-k, -k + 1, \ldots, k - 1, k\} \), \( (u, v) \in K^2 \), and \( y \in T \setminus \{0\} \),
\[
Y_{F,d,u,v}(y) = \{(t, u, v) \in G(y) : \{(t', u', v') \in G(y) : t' < t \text{ and } (u', v') \in F\} = d\}.
\]

(g) For \( F \subseteq K^2 \), \( d \in \{-k, -k + 1, \ldots, k - 1, k\} \), \( (u, v) \in K^2 \) and \( y \in T \setminus \{0\} \),
we define \( \sigma_{F,d,u,v}(y) \in \{-k, -k + 1, \ldots, k - 1, k\} \) by
\[
\sigma_{F,d,u,v}(y) \equiv |Y_{F,d,u,v}(y)|.
\]

Lemma 2.10. Let \( r \) be a strongly increasing idempotent in \( \beta T \), let \( s \in \{1, 2, \ldots, k\} \), and let \( \tilde{c} = \langle c_1, c_2, \ldots, c_s \rangle \) be a compressed sequence in \( A \cup B \). Let \( R \) denote a member of \( r \) on which the functions \( \theta_1 \) and \( \theta_2 \) are constant, the functions \( y \mapsto \varphi_{u,v}(c_i y) \) are constant for each \( i \in \{1, 2, \ldots, s\} \), and the functions \( y \mapsto \sigma_{F,d,u,v}(c_i y) \) are constant for each \( F \subseteq K^2 \), each \( d \in \{-k, -k + 1, \ldots, k - 1, k\} \), each \( (u, v) \in K^2 \), and each \( i \in \{1, 2, \ldots, s\} \).

Therefore, as in the last paragraph of the proof of Lemma 2.8, if \( (u, v) \in P(x) \) and \( j \in \{1, 2, \ldots, s\} \), then \( \varphi_{u,v}(c_j w_j) = 0 \).

Let \( i \in \{1, 2, \ldots, s\} \) be given. Let \( t \in \text{supp}(c_i w_i) \). Then
\[
L_i(x) = \{(t', u', v') \in G_P(x) : t' < t\} = \{(t', u', v') \in G_P(c_i w_i) : t' < t\} \cup \bigcup_{j=1}^{i-1} \left( \{(\delta(w_j), \theta_1(c_j w_j), \theta_2(c_{j+1} w_{j+1})) \} \cup \bigcup_{(u', v') \in P(x)} \{(t', u', v') : t' \in G_{u', v'}(c_j w_j)\}\right).
\]

(If \( i = 1 \), the above reduces to \( L_i(x) = \{(t', u', v') \in G_P(c_i w_1) : t' < t\}\).)

Given \( (u', v') \in P(x) \) and \( j \in \{1, 2, \ldots, i - 1\} \), \( |\{(t', u', v') : t' \in G_{u',v'}(c_j w_j)\}| = \varphi_{u', v'}(c_j w_j) \) and \( \varphi_{u', v'}(c_j w_j) = 0 \), so
\[
|L_i(x)| \equiv |\{(t', u', v') \in G_P(c_i w_i) : t' < t\}| + i - 1.
\]

In particular \( |L_i(x)| \equiv l \) if and only if
\[
|\{(t', u', v') \in G_P(c_i w_i) : t' < t\}| \equiv l - i + 1.
\]

Consequently, \( (t, u, v) \in G(c_i w_i) \cap S_i(x) \) if and only if \( (t, u, v) \in G(c_i w_i) \) and \( |\{(t', u', v') \in G(c_i w_i) : t' < t \text{ and } (u', v') \in P(x)\}| \equiv l - i + 1 \).

We still have fixed \( i \in \{1, 2, \ldots, s\} \). Now fix \( (u, v) \in P(x) \). We claim that
\[ \{ t : (t, u, v) \in G(c_i w_i) \cap S_i(x) \} \equiv 0. \]

Define \( d \in \{-k, -k + 1, \ldots, k - 1, k\} \) by \( d \equiv l - i + 1 \). Then

\[ \{ t : (t, u, v) \in G(c_i w_i) \cap S_i(x) \} \equiv |Y_{P(x),d,u,v}(c_i w_i)|. \]

So it suffices to show that \( |Y_{P(x),d,u,v}(c_i w_i)| \equiv 0. \)

We can choose \( y \in R^* \) such that \( w_i \ll y \) and \( w_i + y \in R^* \). Then the function \( \sigma_{P(x),d,u,v} \) is constant on \( c_i R_i \), so

\[ \sigma_{P(x),d,u,v}(c_i w_i) = \sigma_{P(x),d,u,v}(c_i y) = \sigma_{P(x),d,u,v}(c_i w_i + c_i y). \]

We claim that \( |Y_{P(x),d,u,v}(c_i w_i + c_i y)| \equiv |Y_{P(x),d,u,v}(c_i w_i)| + |Y_{P(x),d,u,v}(c_i y)| \).

It will follow that \( |Y_{P(x),d,u,v}(c_i w_i + c_i y)| \equiv 0 \) and this will complete the proof of \((\dagger)\).

To establish the claim, note that if \( (t, u, v) \in G(c_i w_i + c_i y) \), then \((u, v) \neq (\theta_1(c_i w_i), \theta_2(c_i y))\) so \((t, u, v) \in G(c_i w_i + c_i y)\) if and only if either \((t, u, v) \in G(c_i w_i)\) or \((t, u, v) \in G(c_i y)\). (Notice that \((u, v)\) is fixed. We are not claiming that \(G(c_i w_i + c_i y) = G(c_i w_i) \cup G(c_i y)\), which is false.) If \((t, u, v) \in G(c_i w_i)\) and \((u', v') \in P(x)\), then

\[ \{ (t', u', v') \in G(c_i w_i + c_i y) : t' < t \} = \{ (t', u', v') \in G(c_i w_i) : t' < t \}. \]

If \((t, u, v) \in G(c_i y)\) and \((u', v') \in P(x)\), then \( \{ (t', u', v') \in G(c_i w_i + c_i y) : t' < t \} \) \( = \{ (t', u', v') \in G(c_i y) : t' < t \} \cup \{ (t', u', v') : t' \in G_{u',v'}(c_i w_i) \} \) and \( \{ (t', u', v') : t' \in G_{u',v'}(c_i w_i) \} \equiv \varphi_{u',v'}(c_i w_i) = 0 \). Thus \( |Y_{P(x),d,u,v}(c_i w_i + c_i y)| \equiv |Y_{P(x),d,u,v}(c_i w_i)| + |Y_{P(x),d,u,v}(c_i y)| \) as claimed.

Now \( \delta(w_i) \in \text{supp}(c_i w_i) \) and

\[ \{ (t', u', v') \in G_P(c_i w_i) : t' < \delta(w_i) \} = G_P(c_i w_i) = \bigcup_{(u', v') \in P(x)} \{ (t', u', v') : t' \in G_{u',v'}(c_i w_i) \}. \]

Therefore \( \{ (t', u', v') \in G_P(c_i w_i) : t' < \delta(w_i) \} \equiv 0. \) Thus by \((\ast)\), we have \( |L_{\delta(w_i)}(x)| \equiv i - 1 \) so \( |L_{\delta(w_i)}(x)| \equiv l \) if and only if \( i \neq l + 1 \). In particular,

\[ \delta(w_i), \theta_1(c_i w_i), \theta_2(c_i w_i) \in S_i(x) \text{ and if } i \neq l + 1, \text{ then} \]

\( \delta(w_i), \theta_1(c_i w_i), \theta_2(c_i w_i) \notin S_i(x). \)

Thus, if \( l \leq s - 2 \) and \((u, v) = (\theta_1(c_i w_i), \theta_2(c_i w_i))\), then \( \{ t : (t, u, v) \in S_i(x) \} = \{ \delta(w_i) \} \cup \bigcup_{j=1}^{s-1} \{ t : (t, u, v) \in G(c_i w_i) \cap S_i(x) \} \) so by \((\dagger)\),

\[ \{ t : (t, u, v) \in S_i(x) \} \equiv 1. \text{ Consequently, } \theta_1(c_i w_i), \theta_2(c_i w_i) \notin T_i(x). \]

Finally, if either \( l > s - 2 \) or \((u, v) \neq (\theta_1(c_i w_i), \theta_2(c_i w_i))\), then \( \{ t : (t, u, v) \in S_i(x) \} = \bigcup_{j=1}^{s-1} \{ t : (t, u, v) \in G(c_i w_i) \cap S_i(x) \} \) so by \((\dagger)\),

\[ \{ t : (t, u, v) \in S_i(x) \} \equiv 0 \text{ and thus } (u, v) \notin T_i(x). \]

We now define a finite coloring \( \Gamma \) of \( T \setminus \{0\} \) by agreeing that \( \Gamma(x) = \Gamma(y) \) if and only if

1. \( \theta_1(x) = \theta_1(y), \)
2. \( \theta_2(x) = \theta_2(y). \)
(3) \( \varphi_{u,v}(x) = \varphi_{u,v}(y) \) for all \( (u,v) \in K^2 \), and

(4) \( T_l(x) = T_l(y) \) for all \( l \in \{0,1,\ldots,k-2\} \).

We claim this coloring is as required to complete the proof of Theorem 2.3.

Suppose instead we have strongly increasing idempotents \( p \) and \( q \) in \( \beta T \) and a color class \( D \) of \( \Gamma \) which is a member of both \( a_1p + a_2p + \ldots + a_mp \) and \( b_1q + b_2q + \ldots + b_kq \).

Let \( P \in p \) and \( Q \in q \) be sets on which all of the functions mentioned in the statement of Lemma 2.10 are constant. Suppose also that, for every \( y \in P \), \( \{z \in P : y \ll z\} \in p \), and for every \( y \in Q \), \( \{z \in Q : y \ll z\} \in q \). Pick \( w_1, w_2, \ldots, w_m \) in \( P^* \) such that \( w_i \ll w_{i+1} \) for all \( i \in \{1,2,\ldots,m-1\} \) and pick \( z_1, z_2, \ldots, z_k \) in \( Q^* \) such that \( z_i \ll z_{i+1} \) for all \( i \in \{1,2,\ldots,k-1\} \). Let \( x = a_1w_1 + a_2w_2 + \ldots + a_mw_m \) and let \( y = b_1z_1 + b_2z_2 + \ldots + b_kz_k \). By Lemma 2.10, for each \( l \in \{0,1,\ldots,m-2\} \), \( T_l(x) = \{ (\theta_1(a_{l+1}w_{l+1}), \theta_2(a_{l+2}w_{l+2})) \} \) and for each \( l \in \{0,1,\ldots,k-2\} \), \( T_l(y) = \{ (\theta_1(b_{l+1}z_{l+1}), \theta_2(b_{l+2}z_{l+2})) \} \). Also, if \( m-2 < l \leq k-2 \), then \( T_l(x) = \emptyset \).

We now claim that \( m = k \). Indeed, if \( m < k \), then by Lemma 2.10, \( \emptyset = T_{k-2}(x) = T_{k-2}(y) = \{ (\theta_1(b_{k-1}z_{k-1}), \theta_2(b_kz_k)) \} \), a contradiction.

By Lemma 2.10, for each \( i \in \{1,2,\ldots,k-1\} \), \( \theta_1(a_iw_i) = \theta_1(b_iz_i) \). Also, \( \theta_1(a_kw_k) = \theta_1(x) = \theta_1(y) = \theta_1(b_kz_k) \) and thus for each \( i \in \{1,2,\ldots,k\} \), \( \theta_1(a_iw_i) = \theta_1(b_iz_i) \).

We are supposing that \( \bar{b} \) is not a rational multiple of \( \bar{a} \) so pick the first \( s \in \{2,3,\ldots,m\} \) such that \( b_s/a_s \neq b_1/a_1 \). Then

\[
\psi(a_1(w_s)_{\delta(w_s)}) = \theta_1(a_1w_s) = \theta_1(a_1w_1) = \theta_1(b_1z_1) = \theta_1(b_1z_k) = \psi(b_1(z_s)_{\delta(z_s)})
\]

so by Lemma 2.1,

\[
\psi(a_s(w_s)_{\delta(w_s)}) = \psi(a_s(w_s)_{\delta(w_s)}) = \psi(\frac{a_s}{a_1}a_1(w_s)_{\delta(w_s)}) \neq \psi(\frac{b_s}{b_1}b_1(z_s)_{\delta(z_s)}) = \psi(b_s(z_s)_{\delta(z_s)}) \neq \theta_1(b_s(z_s)),
\]

a contradiction. \( \square \)

**Lemma 2.11.** Let \( r \) be a strongly increasing idempotent in \( \beta T \), let \( s \in \mathbb{N} \), and let \( \langle c_i \rangle_{i=1}^s \) be a sequence in \( \mathbb{Z} \setminus \{0\} \). Let \( R \subseteq T \setminus \{0\} \) be a member of \( r \), with the property that for each \( y \in R \), \( \{z \in R : y \ll z\} \in r \). Let

\[
C = \{ c_1w_1 + c_2w_2 + \ldots + c_sw_s : \ w_1, \ldots, w_s \in R \text{ and for all } i \in \{1,2,\ldots,s-1\}, \, w_i \ll w_{i+1} \}.
\]

Then \( C \in c_1r + c_2r + \ldots + c_r r \).

**Proof.** We proceed by induction on \( s \). Our claim is clearly true if \( s = 1 \). So assume that \( s > 1 \) and that our claim holds for \( s-1 \). Let \( S \in c_1r + c_2r + \ldots + c_{s-1}r \). Since \( \{ y \in T \setminus \{0\} : y + c_sr \in S \} \in c_1r + c_2r + \ldots + c_{s-1}r \), it follows from our inductive assumption that we can choose \( w_1, w_2, \ldots, w_{s-1} \in R \) such that \( c_1w_1 + c_2w_2 + \ldots + c_{s-1}w_{s-1} + c_sr \in S \) and \( w_i \ll w_{i+1} \) for every \( i < s-2 \). We can then choose \( w_s \in R \) such that \( w_{s-1} \ll w_s \) and \( c_1w_1 + c_2w_2 + \ldots + c_{s-1}w_{s-1} + c_sw_s \in S \). So \( C \cap S = \emptyset \). \( \square \)
Corollary 2.12. Let \(k,m \in \mathbb{N}\) and let \(\kappa\) be an infinite cardinal. Let \(\vec{a} = \langle a_1, a_2, \ldots, a_m \rangle\) and \(\vec{b} = \langle b_1, b_2, \ldots, b_k \rangle\) be compressed sequences in \(\mathbb{Z}\) \(\setminus\{0\}\) such that \(\vec{b}\) is not a rational multiple of \(\vec{a}\). Let \(T = \bigoplus_{\sigma < \kappa} \mathbb{Q}\). There is a finite coloring of \(T \setminus \{0\}\) such that there do not exist strongly increasing sequences \(\langle x_n \rangle_{n=1}^\infty\) and \(\langle y_n \rangle_{n=1}^\infty\) in \(T\) \(\setminus\{0\}\) with \(MT(\vec{a}, \langle x_n \rangle_{n=1}^\infty) \cup MT(\vec{b}, \langle y_n \rangle_{n=1}^\infty)\) monochromatic.

Proof. Let \(\Gamma\) be a finite coloring of \(T\) \(\setminus\{0\}\) as guaranteed by Theorem 2.3 and suppose we have strongly increasing sequences \(\langle x_n \rangle_{n=1}^\infty\) and \(\langle y_n \rangle_{n=1}^\infty\) in \(T\) \(\setminus\{0\}\) and a color class \(D\) of \(\Gamma\) such that \(MT(\vec{a}, \langle x_n \rangle_{n=1}^\infty) \cup MT(\vec{b}, \langle y_n \rangle_{n=1}^\infty) \subseteq D\). Pick an idempotent \(p \in \cap_{n=1}^\infty FS(\langle x_n \rangle_{n=1}^\infty)\) and an idempotent \(q \in \cap_{n=1}^\infty FS(\langle y_n \rangle_{n=1}^\infty)\). As we have observed, \(p\) and \(q\) are strongly increasing. By Lemma 2.11, with \(R = FS(\langle x_n \rangle_{n=1}^\infty)\), \(MT(\vec{a}, \langle x_n \rangle_{n=1}^\infty) \in a_1 p + a_2 p + \ldots + a_m p\) and, taking \(R = FS(\langle y_n \rangle_{n=1}^\infty)\), \(MT(\vec{b}, \langle y_n \rangle_{n=1}^\infty) \in b_1 q + b_2 q + \ldots + b_k q\). This contradicts Theorem 2.3.

Lemma 2.13. Let \((S,+)\) and \((T,+\)) be discrete commutative groups, let \(\gamma : T \to S\) be a homomorphism, and let \(\vec{\gamma} : \beta T \to \beta S\) be its continuous extension. Then for all \(p, q \in \beta T\) and all \(a, b \in \mathbb{Z}\) \(\setminus\{0\}\), \(\vec{\gamma}(ap + bq) = a\vec{\gamma}(p) + b\vec{\gamma}(q)\).

Proof. We are claiming that \(\vec{\gamma} \circ \rho_{pq} \circ \vec{\gamma} \text{ and } \rho_{b\vec{\gamma}(q)} \circ \vec{\gamma} \text{ agree on } \beta T\). Since both are continuous functions, it suffices to show that they agree on \(T\), so let \(x \in T\). We claim \(\vec{\gamma}(ax + bq) = a\vec{\gamma}(x) + b\vec{\gamma}(q)\). To see that \(\vec{\gamma} \circ \lambda_{ax} \circ \vec{\gamma} \text{ and } \lambda_{b\vec{\gamma}(q)} \circ \vec{\gamma} \text{ agree on } T\) it suffices that they agree on \(T\) so let \(y \in T\). Then \(\vec{\gamma}(ax + bq) = a\vec{\gamma}(x) + b\vec{\gamma}(y)\) as required.

Theorem 2.14. Let \(k, m \in \mathbb{N}\) and let \(\kappa > 0\) be a cardinal. Let \(\vec{a} = \langle a_1, \ldots, a_m \rangle\) and \(\vec{b} = \langle b_1, \ldots, b_k \rangle\) be compressed sequences in \(\mathbb{Z}\) \(\setminus\{0\}\) such that \(\vec{b}\) is not a rational multiple of \(\vec{a}\). Let \(T = \bigoplus_{\sigma < \kappa} \mathbb{Q}\). Then there do not exist idempotents \(p\) and \(q\) in \(\beta T\) \(\setminus\{0\}\) such that \(a_1 p + \ldots + a_m p = b_1 q + \ldots + b_k q\).

Proof. Suppose the conclusion fails and let \(\kappa\) be the first cardinal for which the conclusion fails. By Theorem 1.5, \(\kappa > 1\).

Let \(n < \min\{\kappa, \omega\}\), let \(\pi_n : T \to \mathbb{Q}\) be the projection defined by \(\pi_n(x) = x_n\) and let \(\pi_n : \beta T \to \beta \mathbb{Q}\) be its continuous extension. By Lemma 2.13, \(\pi_n(p)\) and \(\pi_n(q)\) are idempotents in \(\beta \mathbb{Q}\) and \(a_1 \pi_n(p) + \ldots + a_m \pi_n(p) = b_1 \pi_n(q) + \ldots + b_k \pi_n(q)\) so by assumption either \(\pi_n(p) = 0\) or \(\pi_n(q) = 0\). But by [2, Theorem 4.31], \(\mathbb{Q}^*\) is a left ideal of \(\beta \mathbb{Q}\) so the equation
\[
a_1 \pi_n(p) + \ldots + a_m \pi_n(p) = b_1 \pi_n(q) + \ldots + b_k \pi_n(q)
\]
implies that \(\pi_n(p) = \pi_n(q) = 0\). Consequently, \(\{x \in T : x_n = 0\}\) \(\in p \cap q\).

If \(\kappa < \omega\), one then has that \(\bigcap_{n<\kappa} \{x \in T : x_n = 0\}\) \(\in p \cap q\). That is \(p = q = 0\), a contradiction. Thus we have that \(\kappa \geq \omega\). For each \(\sigma < \kappa\), let \(C_\sigma = \{x \in T \setminus \{0\} : (\forall \tau < \sigma)(x_\tau = 0)\}\). We claim that \(p, q \in \bigcap_{\sigma < \kappa} C_\sigma\). If \(\sigma < \omega\), then \(C_\sigma = \bigcap_{n<\sigma} \{x \in T : x_n = 0\}\) \(\setminus\{0\}\). So if \(\kappa = \omega\), the claim is established.
Assume that $\kappa > \omega$ and let $\omega \leq \sigma < \kappa$. Let $\pi : T \to \bigoplus_{T<\sigma} \mathbb{Q}$ be the natural projection and let $\overline{\pi} : \beta T \to \beta \bigoplus_{T<\sigma} \mathbb{Q}$ be its continuous extension. By Lemma 2.13, $\overline{\pi}(p)$ and $\overline{\pi}(q)$ are idempotents in $\beta \bigoplus_{T<\sigma} \mathbb{Q}$ and
\[ a_{1} \overline{\pi}(p) + \ldots + a_{m} \overline{\pi}(p) = b_{1} \overline{\pi}(q) + \ldots + b_{k} \overline{\pi}(q). \]
Let $\mu = |\sigma|$. Then $\bigoplus_{T<\sigma} \mathbb{Q}$ and $\bigoplus_{T<\mu} \mathbb{Q}$ are isomorphic (and discrete) so $\beta \bigoplus_{T<\sigma} \mathbb{Q}$ and $\beta \bigoplus_{T<\mu} \mathbb{Q}$ are topologically and algebraically isomorphic. Consequently, by the assumption that $\kappa$ is the smallest cardinal for which the conclusion of the theorem fails, we must have that $\overline{\pi}(p) = 0$ or $\overline{\pi}(q) = 0$. And this in turn forces the conclusion that $\overline{\pi}(p) = \overline{\pi}(q) = 0$. So $C_{\sigma} \in p \cap q$.

We thus have that $p,q \in \bigcap_{T<\kappa} \overline{C}_{T}$ as claimed. It follows that $p$ and $q$ are strongly increasing idempotents in $\beta T$. But this contradicts Theorem 2.3.

We get the strongest possible conclusion for preventing equality of linear expressions in direct sums of $\mathbb{Q}$.

**Corollary 2.15.** Let $k,m \in \mathbb{N}$, let $\kappa > 0$ be a cardinal, and let $T = \bigoplus_{T<\kappa} \mathbb{Q}$.

Let $\bar{a} = \langle a_{1},a_{2},\ldots,a_{m} \rangle$ and $\bar{b} = \langle b_{1},b_{2},\ldots,b_{k} \rangle$ be compressed sequences in $\mathbb{Z} \setminus \{0\}$. There exist idempotents $p$ and $q$ in $\beta T \setminus \{0\}$ such that $a_{1}p + \ldots + a_{m}p = b_{1}q + \ldots + b_{k}q$ if and only if $\bar{b}$ is a rational multiple of $\bar{a}$.

**Proof.** The necessity follows from Theorems 2.14 and 1.5.

For the sufficiency, by Theorem 1.5, there exist idempotents $p$ and $q$ in $\beta \mathbb{Q} \setminus \{0\}$ such that $a_{1}p + \ldots + a_{m}p = b_{1}q + \ldots + b_{k}q$. If one lets
\[ p' = \{ A \subseteq T : \pi_{0}[A] \in p \} \quad \text{and} \quad q' = \{ A \subseteq T : \pi_{0}[A] \in q \}, \]

it is a routine exercise to show that $p'$ and $q'$ are idempotents in $\beta T \setminus \{0\}$ such that $a_{1}p' + \ldots + a_{m}p' = b_{1}q' + \ldots + b_{k}q'$.

We can provide half of the answer to Question 1.1.

**Corollary 2.16.** Let $G$ be a torsion free discrete commutative group, let $k,m \in \mathbb{N}$, and let $\bar{a} = \langle a_{1},a_{2},\ldots,a_{m} \rangle$ and $\bar{b} = \langle b_{1},b_{2},\ldots,b_{k} \rangle$ be compressed sequences in $\mathbb{Z} \setminus \{0\}$ which are not rational multiples of each other. There do not exist idempotents $p$ and $q$ in $\beta G \setminus \{0\}$ such that $a_{1}p + a_{2}p + \ldots + a_{m}p = b_{1}q + b_{2}q + \ldots + b_{k}q$.

**Proof.** There is a cardinal $\kappa$ such that $G$ can be embedded in $\bigoplus_{T<\kappa} \mathbb{Q}$.

**3. Separating Milliken-Taylor systems**

We have mentioned that Milliken-Taylor systems are partition regular. In fact, a stronger statement holds.

**Definition 3.1.** Let $(S,+)$ be a commutative semigroup and let $(x_{n})_{n=1}^{\infty}$ and $(y_{n})_{n=1}^{\infty}$ be sequences in $S$. Then $(x_{n})_{n=1}^{\infty}$ is a sum subsystem of $(y_{n})_{n=1}^{\infty}$ if and only if there is a sequence $(F_{n})_{n=1}^{\infty}$ of finite nonempty subsets of $\mathbb{N}$ such that $F_{n} < F_{n+1}$ for each $n$ and $x_{n} = \sum_{t \in F_{n}} y_{t}$ for each $n$. 

12
Theorem 3.2. Let $k, r \in \mathbb{N}$, let $\vec{a} = (a_1, \ldots, a_k)$ be a compressed sequence in $\mathbb{Z} \setminus \{0\}$, let $(G, +)$ be a commutative group, and let $\langle y_n \rangle_{n=1}^{\infty}$ be a sequence in $G$. If $MT(\vec{a}, \langle y_n \rangle_{n=1}^{\infty}) = \bigcup_{i=1}^{r} A_i$, then there exist $i \in \{1, 2, \ldots, r\}$ and a sum subsystem $\langle x_n \rangle_{n=1}^{\infty}$ of $\langle y_n \rangle_{n=1}^{\infty}$ such that $MT(\vec{a}, \langle x_n \rangle_{n=1}^{\infty}) \subseteq A_i$.

Proof. [3, Theorem 1.3].

The proof of the following corollary uses a standard technique.

Corollary 3.3. Let $m, k \in \mathbb{N}$ and let $\vec{a} = (a_1, \ldots, a_m)$ and $\vec{b} = (b_1, \ldots, b_k)$ be compressed sequences in $\mathbb{Z} \setminus \{0\}$ such that $\vec{b}$ is not a rational multiple of $\vec{a}$. Then there is a 2-coloring of $Q \setminus \{0\}$ with the property that there do not exist sequences $\langle x_n \rangle_{n=1}^{\infty}$ and $\langle y_n \rangle_{n=1}^{\infty}$ in $Q \setminus \{0\}$ with $MT(\vec{a}, \langle x_n \rangle_{n=1}^{\infty}) \cup MT(\vec{b}, \langle y_n \rangle_{n=1}^{\infty})$ monochromatic.

Proof. Pick by Theorem 3.2, $r \in \mathbb{N}$ and a function $\psi : \psi \setminus \{0\} \to \{1, 2, \ldots, r\}$ such that there do not exist sequences $\langle x_n \rangle_{n=1}^{\infty}$ and $\langle y_n \rangle_{n=1}^{\infty}$ in $Q \setminus \{0\}$ with

$$MT(\vec{a}, \langle x_n \rangle_{n=1}^{\infty}) \cup MT(\vec{b}, \langle y_n \rangle_{n=1}^{\infty})$$

monochromatic. Let

$$J = \{ i \in \{1, 2, \ldots, r\} : (\exists \langle x_n \rangle_{n=1}^{\infty})(MT(\vec{a}, \langle x_n \rangle_{n=1}^{\infty}) \subseteq \psi^{-1}([i])) \}.$$

Let $A_1 = \bigcup_{i \in J} \psi^{-1}([i])$ and let $A_2 = Q \setminus ((\{0\} \cup A_1)$. Then by Theorem 3.2, there is no sequence $\langle y_n \rangle_{n=1}^{\infty}$ with $MT(\vec{b}, \langle y_n \rangle_{n=1}^{\infty}) \subseteq A_1$ and there is no sequence $\langle x_n \rangle_{n=1}^{\infty}$ with $MT(\vec{a}, \langle x_n \rangle_{n=1}^{\infty}) \subseteq A_2$.

The following theorem is the only complete answer we can give for separating Milliken-Taylor systems in direct sums.

Theorem 3.4. Let $m, k, r, l \in \mathbb{N}$. Let $(G, +)$ be a commutative group and let $\vec{a} = (a_1, a_2, \ldots, a_m)$ and $\vec{b} = (b_1, b_2, \ldots, b_k)$ be compressed sequences in $\mathbb{Z} \setminus \{0\}$. Assume that there is an $r$-coloring of $G \setminus \{0\}$ with the property that there do not exist sequences $\langle x_n \rangle_{n=1}^{\infty}$ and $\langle y_n \rangle_{n=1}^{\infty}$ in $G \setminus \{0\}$ with

$$MT(\vec{a}, \langle x_n \rangle_{n=1}^{\infty}) \cup MT(\vec{b}, \langle y_n \rangle_{n=1}^{\infty})$$

monochromatic. Let $T = \bigoplus_{i \in \mathbb{Z}} G$. Then there is an $r$-coloring of $T \setminus \{0\}$ with the property that there do not exist sequences $\langle x_n \rangle_{n=1}^{\infty}$ and $\langle y_n \rangle_{n=1}^{\infty}$ in $T \setminus \{0\}$ with $MT(\vec{a}, \langle x_n \rangle_{n=1}^{\infty}) \cup MT(\vec{b}, \langle y_n \rangle_{n=1}^{\infty})$ monochromatic.

Proof. Let $\psi$ be an $r$-coloring of $G \setminus \{0\}$ with the property that there do not exist sequences $\langle x_n \rangle_{n=1}^{\infty}$ and $\langle y_n \rangle_{n=1}^{\infty}$ in $G \setminus \{0\}$ with

$$MT(\vec{a}, \langle x_n \rangle_{n=1}^{\infty}) \cup MT(\vec{b}, \langle y_n \rangle_{n=1}^{\infty})$$

monochromatic. Define an $r$-coloring $\tau$ of $T \setminus \{0\}$ by $\tau(x) = \psi(x_{\alpha(x)})$. Suppose we have sequences $\langle x_n \rangle_{n=1}^{\infty}$ and $\langle y_n \rangle_{n=1}^{\infty}$ in $T$ with

$$MT(\vec{a}, \langle x_n \rangle_{n=1}^{\infty}) \cup MT(\vec{b}, \langle y_n \rangle_{n=1}^{\infty})$$

13
monochromatic with respect to $\tau$.

By Theorem 3.2, pick $i < l$, $j < l$, a sum subsystem $\langle z_n \rangle_{n=1}^\infty$ of $\langle x_n \rangle_{n=1}^\infty$, and a sum subsystem $\langle w_n \rangle_{n=1}^\infty$ of $\langle y_n \rangle_{n=1}^\infty$ such that for all $u \in MT(\vec{a}, \langle z_n \rangle_{n=1}^\infty)$, $\alpha(u) = i$ and for all $v \in MT(\vec{b}, \langle w_n \rangle_{n=1}^\infty)$, $\alpha(v) = j$. Note that no $m$ terms of $\langle z_n \rangle_{n=1}^\infty$ can have $(z_n)_i = 0$ or else there would be a member $u$ of $MT(\vec{a}, \langle z_n \rangle_{n=1}^\infty)$ with either $u = 0$ or $\alpha(u) \neq i$, so we may assume no term of $\langle z_n \rangle_{n=1}^\infty$ has $(z_n)_i = 0$, and similarly for $\langle w_n \rangle_{n=1}^\infty$. Define sequences $\langle z'_n \rangle_{n=1}^\infty$ and $\langle w'_n \rangle_{n=1}^\infty$ in $G$ by $z'_n = (z_n)_i$ and $w'_n = (w_n)_j$. Then $MT(\vec{a}, \langle z'_n \rangle_{n=1}^\infty) \cup MT(\vec{b}, \langle w'_n \rangle_{n=1}^\infty)$ is monochromatic with respect to $\psi$.

**Corollary 3.5.** Let $m, k, l \in \mathbb{N}$ and let $\vec{a} = \langle a_1, a_2, \ldots, a_m \rangle$ and $\vec{b} = \langle b_1, b_2, \ldots, b_k \rangle$ be compressed sequences in $\mathbb{Z} \setminus \{0\}$ such that $\vec{b}$ is not a rational multiple of $\vec{a}$. Let $T = \bigoplus_{n \leq 1} \mathbb{Q}$. Then there is a 2-coloring of $T \setminus \{0\}$ with the property that there do not exist sequences $\langle x_n \rangle_{n=1}^\infty$ and $\langle y_n \rangle_{n=1}^\infty$ in $T \setminus \{0\}$ with $MT(\vec{a}, \langle x_n \rangle_{n=1}^\infty) \cup MT(\vec{b}, \langle y_n \rangle_{n=1}^\infty)$ monochromatic.

**Proof.** Corollary 3.3 and Theorem 3.4.

**Definition 3.6.** Let $\kappa$ be an infinite cardinal, let $T = \bigoplus_{\sigma < \kappa} \mathbb{Q}$, and let $\langle z_n \rangle_{n=1}^\infty$ be a sequence in $T \setminus \{0\}$.

(a) The sequence $\langle z_n \rangle_{n=1}^\infty$ is of type I if and only if it is strongly increasing.

(b) The sequence $\langle z_n \rangle_{n=1}^\infty$ is of type II if and only if there is some $\sigma < \kappa$ such that for all $n$, $\alpha(z_n) = \sigma$.

(c) The sequence $\langle z_n \rangle_{n=1}^\infty$ is of type III if and only if there is some $\sigma < \kappa$ such that for all $n$, $\delta(z_n) = \sigma$.

**Lemma 3.7.** Let $m \in \mathbb{N}$, let $\vec{a} = \langle a_1, a_2, \ldots, a_m \rangle$ be a compressed sequence in $\mathbb{Z} \setminus \{0\}$, let $\kappa$ be an infinite cardinal, and let $T = \bigoplus_{\sigma < \kappa} \mathbb{Q}$.

1. If $\langle z_n \rangle_{n=1}^\infty$ is a type II sequence in $T \setminus \{0\}$, $\alpha(z_n) = \sigma$ for all $n \in \mathbb{N}$, and $H = \{ x \in T \setminus \{0\} : \alpha(x) = \sigma \}$, then there is a sum subsystem $\langle w_n \rangle_{n=1}^\infty$ of $\langle z_n \rangle_{n=1}^\infty$ such that $FS(\langle w_n \rangle_{n=1}^\infty) \cup MT(\vec{a}, \langle w_n \rangle_{n=1}^\infty) \subseteq H$.

2. If $\langle z_n \rangle_{n=1}^\infty$ is a type III sequence in $T \setminus \{0\}$, $\delta(z_n) = \sigma$ for all $n \in \mathbb{N}$, and $H = \{ x \in T \setminus \{0\} : \delta(x) = \sigma \}$, then there is a sum subsystem $\langle w_n \rangle_{n=1}^\infty$ of $\langle z_n \rangle_{n=1}^\infty$ such that $FS(\langle w_n \rangle_{n=1}^\infty) \cup MT(\vec{a}, \langle w_n \rangle_{n=1}^\infty) \subseteq H$.

**Proof.** The proofs are essentially identical. We shall do the proof for (1). By passing to a subsequence, we may presume that all $\pi_\sigma(z_n)$’s are the same sign and thus $FS(\langle z_n \rangle_{n=1}^\infty) \subseteq H$. By Theorem 3.2, pick a sum subsystem $\langle w_n \rangle_{n=1}^\infty$ of $\langle z_n \rangle_{n=1}^\infty$ such that either $MT(\vec{a}, \langle w_n \rangle_{n=1}^\infty) \subseteq H$ or $MT(\vec{a}, \langle w_n \rangle_{n=1}^\infty) \subseteq T \setminus H$. We claim that the latter is impossible so suppose that $MT(\vec{a}, \langle w_n \rangle_{n=1}^\infty) \subseteq T \setminus H$. Then $a_1 w_1 + a_2 w_2 + \ldots + a_m w_m$ is in $T \setminus H$ so $\pi_\sigma(a_1 w_1 + a_2 w_2 + \ldots + a_m w_m) = 0$. But $\pi_\sigma(a_m w_{m+1}) \neq 0$ so $a_1 w_1 + a_2 w_2 + \ldots + a_m (w_m + w_{m+1}) \in H$.

Theorem 3.8. Let \( k, m \in \mathbb{N} \) and let \( \kappa \) be an infinite cardinal. Let \( \vec{a} = \langle a_1, a_2, \ldots, a_m \rangle \) and \( \vec{b} = \langle b_1, b_2, \ldots, b_k \rangle \) be compressed sequences in \( \mathbb{Z} \setminus \{0\} \) such that \( \vec{b} \) is not a rational multiple of \( \vec{a} \). Let \( T = \bigoplus_{\sigma \leq \kappa} \mathbb{Q} \). There is a finite coloring of \( T \setminus \{0\} \) such that there do not exist sequences \( \langle x_n \rangle_{n=1}^\infty \) and \( \langle y_n \rangle_{n=1}^\infty \) in \( T \setminus \{0\} \) of the same type with \( MT(\vec{a}, \langle x_n \rangle_{n=1}^\infty) \cup MT(\vec{b}, \langle y_n \rangle_{n=1}^\infty) \) monochromatic.

Proof. Let \( T \) be a finite coloring of \( T \setminus \{0\} \) as guaranteed for \( \vec{a} \) and \( \vec{b} \) by Corollary 2.12 and let \( \psi \) be a finite coloring of \( \mathbb{Q} \setminus \{0\} \) as guaranteed for \( \vec{a} \) and \( \vec{b} \) by Theorem 1.5. Define a coloring \( \tau \) of \( T \setminus \{0\} \) by, for \( x \in T \setminus \{0\} \), \( \tau(x) = (\Gamma(x), \psi(x_{\alpha(x)}), \psi(x_{\beta(x)})) \). Suppose that one has sequences \( \langle x_n \rangle_{n=1}^\infty \) and \( \langle y_n \rangle_{n=1}^\infty \) of the same type with \( MT(\vec{a}, \langle x_n \rangle_{n=1}^\infty) \cup MT(\vec{b}, \langle y_n \rangle_{n=1}^\infty) \) monochromatic of color \((i,j,l)\). One has immediately that the sequences are not of type I. Suppose that \( \langle x_n \rangle_{n=1}^\infty \) and \( \langle y_n \rangle_{n=1}^\infty \) are both of type II and pick \( \sigma \) and \( \gamma \) such that for all \( n \in \mathbb{N} \), \( \alpha(x_n) = \sigma \) and \( \alpha(y_n) = \gamma \). Let \( H = \{ x \in T \setminus \{0\} : \alpha(x) = \sigma \} \) and let \( K = \{ x \in T \setminus \{0\} : \alpha(x) = \gamma \} \). By Lemma 3.7 we may pick a sum subsystem \( \langle w_n \rangle_{n=1}^\infty \) of \( \langle x_n \rangle_{n=1}^\infty \) and a sum subsystem \( \langle z_n \rangle_{n=1}^\infty \) of \( \langle y_n \rangle_{n=1}^\infty \) such that \( FS(\langle w_n \rangle_{n=1}^\infty) \cup MT(\vec{a}, \langle w_n \rangle_{n=1}^\infty) \subseteq H \) and \( FS(\langle z_n \rangle_{n=1}^\infty) \cup MT(\vec{b}, \langle z_n \rangle_{n=1}^\infty) \subseteq K \). For each \( n \in \mathbb{N} \), let \( w_n' = \pi_\sigma(w_n) \) and let \( z_n' = \pi_\gamma(z_n) \). Then \( \psi \) is constantly equal to \( j \) on \( MT(\vec{a}, \langle w_n' \rangle_{n=1}^\infty) \cup MT(\vec{b}, \langle z_n' \rangle_{n=1}^\infty) \), a contradiction.

Similarly the sequences cannot both be of type III. \( \square \)

Corollary 3.9. Let \( m, k, l \in \mathbb{N} \), let \( T = \bigoplus_{n<\omega} \mathbb{Q} \), and let \( \vec{a} = \langle a_1, a_2, \ldots, a_m \rangle \), \( \vec{b} = \langle b_1, b_2, \ldots, b_k \rangle \), and \( \vec{c} = \langle c_1, c_2, \ldots, c_l \rangle \) be compressed sequences in \( \mathbb{Z} \setminus \{0\} \), no one of which is a rational multiple of another. There is a finite coloring of \( T \setminus \{0\} \) such that there do not exist sequences \( \langle x_n \rangle_{n=1}^\infty \), \( \langle y_n \rangle_{n=1}^\infty \), and \( \langle z_n \rangle_{n=1}^\infty \) in \( T \setminus \{0\} \) such that \( MT(\vec{a}, \langle x_n \rangle_{n=1}^\infty) \cup MT(\vec{b}, \langle y_n \rangle_{n=1}^\infty) \cup MT(\vec{c}, \langle z_n \rangle_{n=1}^\infty) \) is monochromatic.

Proof. Any sequence in \( T \setminus \{0\} \) has a subsequence of type I or a subsequence of type II, so this is an immediate consequence of Theorem 3.8. \( \square \)

It is a consequence of Corollary 2.16 that we can prevent equality of linear expressions in \( \mathbb{B}_d \) and its direct sums.

Question 3.10. Let \( m, k, l \in \mathbb{N} \) and let \( \vec{a} = \langle a_1, a_2, \ldots, a_m \rangle \), \( \vec{b} = \langle b_1, b_2, \ldots, b_k \rangle \), and \( \vec{c} = \langle c_1, c_2, \ldots, c_l \rangle \) be compressed sequences in \( \mathbb{Z} \setminus \{0\} \), no one of which is a rational multiple of another. Is there a finite coloring of \( \mathbb{R} \setminus \{0\} \) such that there do not exist sequences \( \langle x_n \rangle_{n=1}^\infty \), \( \langle y_n \rangle_{n=1}^\infty \), and \( \langle z_n \rangle_{n=1}^\infty \) in \( \mathbb{R} \setminus \{0\} \) such that \( MT(\vec{a}, \langle x_n \rangle_{n=1}^\infty) \cup MT(\vec{b}, \langle y_n \rangle_{n=1}^\infty) \cup MT(\vec{c}, \langle z_n \rangle_{n=1}^\infty) \) is monochromatic?

We conclude by showing that we can separate Milliken-Taylor systems in \((\mathbb{N}, \cdot)\).

Theorem 3.11. Let \( \kappa > 0 \) be a cardinal and let \( T = \bigoplus_{\sigma \leq \kappa} \omega \). Let \( m, k, \in \mathbb{N} \) and let \( \vec{a} = \langle a_1, a_2, \ldots, a_m \rangle \) and \( \vec{b} = \langle b_1, b_2, \ldots, b_k \rangle \) be compressed sequences in \( \mathbb{Z} \setminus \{0\} \), which are not rational multiples of each other. There is a finite coloring of \( T \) with the property that there are no sequences \( \langle x_n \rangle_{n=1}^\infty \) and \( \langle y_n \rangle_{n=1}^\infty \) in \( T \setminus \{0\} \) for which \( MT(\vec{a}, \langle x_n \rangle_{n=1}^\infty) \cup MT(\vec{b}, \langle y_n \rangle_{n=1}^\infty) \) is monochromatic. In particular, the systems \( MT(\vec{a}, \langle x_n \rangle_{n=1}^\infty) \) and \( MT(\vec{b}, \langle y_n \rangle_{n=1}^\infty) \) can be separated over \((\mathbb{N}, \cdot)\).
Proof. Let $G = \bigoplus_{\sigma < \kappa} \mathbb{Z}$. Define $h : G \to \mathbb{Z}$ by $h(x) = \sum_{\sigma < \kappa} x_{\sigma}$. Observe that $h$ is a group homomorphism and $h[T \setminus \{0\}] = \omega \setminus \{0\}$. Pick by Theorem 1.5 a finite coloring $\Gamma$ of $\mathbb{Z} \setminus \{0\}$ such that there are no sequences $(s_n)_{n=1}^{\infty}$ and $(t_n)_{n=1}^{\infty}$ in $\mathbb{Z} \setminus \{0\}$ for which $MT(\vec{a}, (s_n)_{n=1}^{\infty}) \cup MT(\vec{b}, (t_n)_{n=1}^{\infty})$ is monochromatic with respect to $\Gamma$. Let $\psi$ be the restriction of $\Gamma \circ h$ to $T \setminus \{0\}$. Then $\psi$ is a finite coloring of $T \setminus \{0\}$. If there were sequences $(x_n)_{n=1}^{\infty}$ and $(y_n)_{n=1}^{\infty}$ in $T \setminus \{0\}$ with $MT(\vec{a}, (x_n)_{n=1}^{\infty}) \cup MT(\vec{b}, (y_n)_{n=1}^{\infty})$ monochromatic with respect to $\psi$, then one would have $MT(\vec{a}, (h(x_n))_{n=1}^{\infty}) \cup MT(\vec{b}, (h(y_n))_{n=1}^{\infty})$ monochromatic with respect to $\Gamma$.

The “in particular” conclusion holds because $(\mathbb{N}, \cdot)$ is isomorphic to $\bigoplus_{\sigma < \omega} \omega$.
